Hybrid Control of the Boost Converter: Robust Global Stabilization

Thomas A.F. Theunisse, Jun Chai, Ricardo G. Sanfelice, and W.P. Maurice H. Heemels

Abstract—In this paper we consider the modeling and (robust) control of a DC-DC boost converter. In particular, we derive a mathematical model consisting of a constrained switched differential inclusion that includes all possible modes of operation of the converter. The obtained model is carefully selected to be amenable for the study of various important robustness properties. By exploiting this model we design a control algorithm that induces robust, global asymptotic stability of a desired output voltage value. The guaranteed robustness properties ensure proper operation of the converter in the presence of spatial regularization to reduce the high rate of switching. The establishment of these properties is enabled by recent tools for the study of robust stability in hybrid systems. Simulations illustrating the main results are included.

I. INTRODUCTION

The increasing number of renewable energy sources and distributed generators requires new strategies for the operation and management of the electricity grid in order to maintain or even to improve the power-supply reliability and quality. Power electronics play a key role in distributed generation and in integration of renewable sources into the electrical grid [1]. A recent challenge for these systems is the unavoidable variability of the power obtained from renewable resources, which, in turn, demands conversion technology that robustly adapts to changes in the supplies and demands.

One type of converter that is widely used in energy conversion is the DC-DC Boost converter. This converter draws power from a DC voltage source and supplies power to a load at a higher DC voltage value. Different approaches have been employed in the literature for the analysis and design of such converters. Arguably, the most popular method used to control such converters is Pulse-Width Modulation (PWM). In PWM-based controllers, the switch in the circuit is turned on at the beginning of each switching period and is turned off when the reference value is lower than a certain carrier signal [2]. In [3], the two steady state configurations of the circuit are averaged, leading to a single differential equation model. More recently, a renewed interest in power converters originated from the rise of switching/hybrid modeling paradigms [4]–[9], and new perspectives on their control were proposed, including time-based switching, state-event triggered control, and optimization-based control.

In this paper, motivated by the need of converters that robustly adapt to changes in renewable energy systems, we consider the modeling and robust control of a DC-DC boost converter. As a difference to previous models capturing only steady state modes of operation (see, e.g., [4], [5]), inspired by [9], we propose a model that includes all possible modes of operation of the converter. Due to this, we guarantee that both transient behavior and every possible state of the system is captured by the model. Our proposed model for the Boost converter consists of a switching differential inclusion with constraints. Using hybrid systems tools, we study the properties induced by a controller that triggers switches of the differential inclusion based on the value of the internal current and output voltage of the converter as well as on the value of the state of the controller (a logic variable). We formally prove that the controller we employ, which follows the one first proposed in [5] and studied by simulations therein, induces robust, global asymptotic stability of a desired output voltage value. The robustness properties guarantee proper operation of the converter in the presence of spatial regularization to relax the rate of switching. The recently developed tools for robust stability in hybrid systems form the enabling techniques to achieve these important results [10].

The remainder of the paper is organized as follows. After introducing notation, the principles of operation of the Boost converter are discussed and our mathematical model is presented in Section II. A switching control law is presented in Section III. In addition, also in Section III, global asymptotic stability for the closed-loop system is proven. The results on robustness are also presented in Section III. In Section IV, simulations are performed to illustrate our results. Finally, concluding remarks are presented in Section V.

Notation: \( \mathbb{R}^n \) denotes \( n \)-dimensional Euclidean space, and \( \mathbb{R} \) denotes the set of real numbers. \( \mathbb{R}_{\geq 0} \) denotes the set of nonnegative real numbers, i.e., \( \mathbb{R}_{\geq 0} = [0, \infty) \). \( \mathbb{N} \) denotes the set of natural numbers including 0, i.e., \( \mathbb{N} = \{0, 1, \ldots\} \). \( \mathbb{B} \) denotes the closed unit ball in a Euclidean space centered at the origin. Given a set \( S \), \( \partial S \) denotes its boundary. Given a vector \( x \in \mathbb{R}^n \), \( |x| \) denotes the Euclidean vector norm. Given a set \( K \subset \mathbb{R}^n \) and a point \( x \in \mathbb{R}^n \), the distance of \( x \) to the set \( K \) is denoted by \( |x|_K := \inf_{y \in K} |x - y| \). We use the notation \( \overline{S} \) to denote the closed convex hull of a set. For \( l \) vectors \( x_i \in \mathbb{R}^n \), \( i = 1, 2, \ldots, l \), we denote the vector obtained by stacking all the vectors in one (column) vector \( x \in \mathbb{R}^n \) with \( n = n_1 + n_2 + \ldots + n_l \) by \( (x_1, x_2, \ldots, x_l) \).
i.e., \((x_1, x_2, \ldots, x_t) = [x_1^T, x_2^T, \ldots, x_t^T]^T\). A function \(\alpha : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}\) is said to be of class \(\mathcal{K}\) if it is continuous, zero at zero and strictly increasing. It is said to be of class \(\mathcal{K}_\infty\) if it is of class \(\mathcal{K}\) and it is unbounded. A function \(\beta : \mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}\) is said to be of class \(\mathcal{KL}\) if \(\beta(t, \cdot)\) is of class \(\mathcal{K}\) for each \(t \geq 0\) and \(\beta(\cdot, s)\) is nonincreasing and satisfies \(\lim_{t \to \infty} \beta(s, t) = 0\) for each \(s \geq 0\).

II. MODELING

In this section we describe the principles of operation of the DC-DC Boost converter. Afterwards, we present a hybrid system model, covering all possible system modes.

A. Principles of Operation

The DC-DC Boost converter is shown in Figure 1. The Boost circuit consists of a capacitor \(c\), an ideal diode \(d\), a DC voltage source \(E\), an inductor \(L\), a resistor \(R\), and an ideal switch \(S\). The voltage across the capacitor is denoted \(v_c\), and the current through the inductor is denoted \(i_L\). The purpose of the circuit is to draw power from the DC voltage source, and supply power to the load at a higher DC voltage value. This task is accomplished by first closing the switch to store energy in the inductor, and then opening the switch to transfer that energy to the capacitor, where it is available to the load.

The presence of switching elements (\(d\) and \(S\)) causes the overall system to be of a switching/hybrid nature. Depending on the (discrete) state of the diode and of the switch, one can distinguish four modes of operation [9]:

- **mode 1**: \((S = 0, d = 1)\)
- **mode 2**: \((S = 1, d = 0)\)
- **mode 3**: \((S = 0, d = 0)\)
- **mode 4**: \((S = 1, d = 1)\)

When the system is in mode 1, in which the switch is open \((S = 0)\) and the diode is conducting \((d = 1)\), the inductor is charged by the input source, which, also offloads power to the resistor. In mode 2, in which the switch is closed \((S = 1)\) and the diode is blocking \((d = 0)\), the inductor is charged by the input source and the capacitor is offloading its charge to the load. In mode 3, the capacitor offloads its charge to the load. Finally, mode 4, in which the switch is closed, the diode is conducting and the voltage in the capacitor is zero, hence only the inductor is charging.

Using the ideal diode model with two modes, given by \(i_d \geq 0, v_d = 0\) (the conducting mode, \(d = 1\)) and \(i_d = 0, v_d \leq 0\) (the blocking mode, \(d = 0\)), we get four different modes with different \(S\) and \(d\) combinations. By analyzing the evolution of \(v_c\) and \(i_L\) for these four modes, we can derive constrained differential equations for each mode. Conveniently, the equations for mode 2 and mode 4 can be combined into a single mode, which with some abuse of notation, we label as mode 2. Following circuit laws, the constrained differential equations for each mode are given in terms of \((v_c, i_L, S)\) as follows:

\[
1: \begin{cases}
S = 0 \\
v_c &= -\frac{1}{RC}v_c + \frac{1}{L}i_L \\
i_L &= \frac{E}{L} \\
i_L > 0, \text{ or } (v_c \leq E, i_L = 0) \\
v_c &\geq 0
\end{cases}
\]

\[
2: \begin{cases}
S = 1 \\
v_c &= -\frac{1}{RC}v_c \\
i_L &= \frac{E}{L} \\
v_c &\geq 0
\end{cases}
\]

\[
3: \begin{cases}
S = 0 \\
v_c &= \frac{1}{RC}v_c \\
i_L &= 0 \\
v_c &> E, i_L = 0
\end{cases}
\]

Therefore, the value of the switch \(S\) determines whether the system is in mode 1/mode 3 \((S = 0)\) or mode 2 \((S = 1)\). Note that it is possible that when \(S\) changes, \(v_c\) and \(i_L\) may not be in the regions of viability in the subsequent mode, in which case \(v_c\) and \(i_L\) should be appropriately reset (e.g., via consistency projectors mapping the state to the algebraic conditions of the subsequent mode [7], [8], [11]). Although, a full model with resets can be derived, see [9], for practical operation of the converter it is clearly undesirable that such resets occur as they may damage the circuit. Therefore our controller will allow \(S = 0\) when \(i_L \geq 0\), and \(S = 1\) only when \(v_c \geq 0\). Indeed, in Section III-A, we propose a controller that guarantees that after every switch of \(S\), the algebraic conditions of the subsequent mode are satisfied.

For convenience, we define \(x := (v_c, i_L)\) and the algebraic constraints for the modes above in terms of sets as follows:

\[
M_1 = \{x \in \mathbb{R}^2 : i_L > 0\} \cup \{x \in \mathbb{R}^2 : v_c \leq E, i_L = 0\},
\]

\[
M_2 = \{x \in \mathbb{R}^2 : v_c \geq 0\},
\]

\[
M_3 = \{x \in \mathbb{R}^2 : v_c > E, i_L = 0\}
\]

Hence, \(S = 0\) is only allowed when \(x \in M_1 \cup M_3\) and \(S = 1\) is only allowed when \(x \in M_2\). Using these restrictions, we can derive a switched differential inclusion encompassing all the modes of operation derived so far.

B. Mathematical Model

In this section, we define a mathematical model of the Boost converter in which the differential equations in each mode define the continuous dynamics. Since the vector field associated with mode 1 is

\[
f_a(x) = \left[\begin{array}{c}
-\frac{1}{RC}v_c + \frac{1}{L}i_L \\
\frac{1}{L}v_c + \frac{E}{L}
\end{array}\right]
\]

and the vector field associated with mode 3 is

\[
f_b(x) = \left[\begin{array}{c}
-\frac{1}{RC}v_c \\
n\end{array}\right]
\]

the resulting vector field for \(S = 0\) is discontinuous. To establish robust asymptotic stability of the upcoming closed-loop system, a Krasovskii regularization of the vector field...
will be performed following ideas in [12], [13]. The system will take the form of a switched differential inclusion with constraints, namely
\[
\dot{x} \in F_S(x) \quad x \in \tilde{M}_S
\]  
where \( S \in \{0, 1\} \) is the position of the switch \( S \), and for each \( S \in \{0, 1\}, F_S(x) \) is the Krasovskii regularization of the vector fields and \( M_S \) is the corresponding regularization of the sets capturing the regions of validity for each mode.

Solutions will be considered in the sense of Krasovskii [12], [13].

A Krasovskii regularization of this vector field is used due to the fact that the discontinuity occurs on a set of measure zero. A Filippov regularization would not account for discontinuities on such sets.

### A. Control Law

Given a desired set-point voltage \( v_c^* > 0 \) and current \( i_L^* > 0 \), let \( x^* = (v_c^*, i_L^*) \) and consider the control Lyapunov function
\[
V(x) = (x - x^*)^T P(x - x^*)
\]
where \( P = \begin{bmatrix} p_{11} & 0 \\ 0 & p_{22} \end{bmatrix} > 0 \). To derive the control law, we compute the inner product between the gradient of \( V \) and the directions belonging to the (set-valued) map \( F_S \) in (1). By analyzing the inner product of each configuration, for each \( S \in \{0, 1\} \) and \( x \in \tilde{M}_S \) we get,
\[
\max_{\xi \in F_S(x)} \langle \nabla V(x), \xi \rangle = \begin{cases} 
\gamma_0(x) & \text{if } S = 0, x \in \tilde{M}_0 \\
\gamma_1(x) & \text{if } S = 1, x \in \tilde{M}_1
\end{cases}
\]

where, for each \( x \in \mathbb{R}^2 \), functions \( \gamma_0 \) and \( \gamma_1 \) are defined as
\[
\gamma_0(x) := 2p_{11}(v_c - v_c^*) + \begin{cases} 
\frac{1}{Re} v_c + \frac{1}{L} i_L & \text{if } S = 0 \\
\frac{1}{Re} v_c + \frac{1}{L} i_L - \frac{E}{L} & \text{if } S = 1
\end{cases}
\]
\[
\gamma_1(x) := 2p_{11}(v_c - v_c^*) + 2p_{22}(i_L - i_L^*) \frac{E}{L}
\]

The sign of the functions \( \gamma_0, \gamma_1 \) will be used to define a state-dependent switching control law assigning the control input \( S \). Let
\[
A_x = \{ x \in \mathbb{R}^2 : v_c = v_c^*, i_L = i_L^* \}
\]
define the isolated point to be stabilized, namely, the point \((v_c^*, i_L^*)\). The following lemma establishes a property of functions \( \gamma_0, \gamma_1 \) that will be used in our stability result in Section III-B.

**Lemma 3.1:** Let \( R, E, p_{11}, p_{22} > 0 \), \( \frac{p_{11}}{Re} = \frac{p_{22}}{L} \), \( v_c^* > E \), and \( i_L^* = \frac{v_c^*}{Re} \). Then, for each \( x \in \mathbb{R}^2 \setminus A_x \), there exists \( S \in \{0, 1\} \) such that
\[
\gamma_S(x) < 0
\]

To obtain a control law that does not result in sliding motions and is robust, following the idea in [5], we propose a logic-based control law that selects the input according to the current active input and the value of the state. To this end, let \( q \in \{0, 1\} \) be a logic state indicating the value of the actual input \( S \). The controller is defined so that switching of \( q \) to \( 1 - q \) occurs only if \( \gamma_q(x) \) becomes zero. Then, when \( x \in \mathbb{R}^2 \setminus A_x \) and \( \gamma_q(x) = 0 \), by Lemma 3.1, \( \gamma_1 - \gamma_q(x) < 0 \), which makes the closed-loop trajectory components \( x \) approach \( A_x \).

The closed-loop system is obtained when \( S \) is assigned to \( q \), namely, \( S = q \). This leads to the hybrid system \( \mathcal{H} \) given by
\[
\begin{bmatrix}
\dot{x} \\
\dot{q}
\end{bmatrix} = \begin{cases} 
F_q(x) & (x, q) \in C \\
0 & (x, q) \in D
\end{cases}
\]

where
\[
C = \{ (x, q) : x \in \tilde{M}_0, \gamma_0(x) \leq 0, q = 0 \} \cup \{ (x, q) : x \in \tilde{M}_1, \gamma_1(x) \leq 0, q = 1 \}
\]
D = \{(x, q) : x \in \tilde{M}_0, \gamma_0(x) = 0, q = 0 \} \cup \{(x, q) : x \in \tilde{M}_1, \gamma_1(x) = 0, q = 1 \}

and

G_q(x) = \begin{cases} \{1\} & \text{if } q = 0, \gamma_0(x) = 0 \\ \{0\} & \text{if } q = 1, \gamma_1(x) = 0 \end{cases}

The flow map \( F \) of the hybrid system \( \mathcal{H} \) is constructed by stacking the map \( F_S \) (with \( S = q \)) of (1) and zero, while the flow set enforces the constraints in (1) as well as those of the switching mechanism of the proposed controller. In this way, the continuous evolution of \( x \) is according to (1) under the effect of the proposed controller, while \( q \) does not change during flows. The jump map \( G \) is such that \( x \) does not change at jumps and \( q \) is toggled at jumps, while the jump set enforces the jumps of the controller within the constraints of (1).

Some sample contour plots and switching boundaries \( \gamma_q(x) = 0 \) of the proposed controller or a particular set of parameters \((x^* = (7, 3.27), E = 5V, R = 3\Omega, c = 0.1F, L = 0.2H, p_{11} = \frac{1}{2}, p_{22} = \frac{1}{2})\) are shown in Figure 2.

![Contour plots](image)

Fig. 2. Contour plots of (upper-left) \( \gamma_0 \), (upper-right) \( \gamma_1 \), and (lower) the switching boundaries \( \gamma_q(x) = 0 \). when \( x^* = (7, 3.27), E = 5V, R = 3\Omega, c = 0.1F, L = 0.2H, p_{11} = \frac{1}{2}, p_{22} = \frac{1}{2} \).

B. Properties of closed-loop system

Solutions to the closed-loop system \( \mathcal{H} \) can evolve continuously and/or discretely depending on flow and jump dynamics. Following [14], we treat the number of jumps as an independent variable \( j \) next to the usual time and we parameterize the hybrid time by \((t, j)\). Solutions to hybrid systems \( \mathcal{H} \) are given in terms of hybrid arcs and hybrid inputs on hybrid time domains. Hybrid time domains are subsets \( E \) of \( \mathbb{R}_{\geq 0} \times \mathbb{N} \) that, for each \((T, J) \in E, E \cap ([0, T] \times \{0, 1, \ldots, J\}) \) can be written as \( \cup_{j=1}^{J-1} ([t_j, t_{j+1}], j) \) for some finite sequence of times \( 0 = t_0 \leq t_1 \leq t_2 \leq \ldots \leq t_J \). A hybrid arc \( \phi \) is a function on a hybrid time domain that, for each \( j \in \mathbb{N}, t \mapsto \phi(t, j) \) is absolutely continuous on the interval \( \{t : (t, j) \in \text{dom} \phi \} \). Then, a solution to the hybrid system \( \mathcal{H} \) is given by a hybrid arc \( \phi \) satisfying the dynamics of \( \mathcal{H} \). A solution \( \phi \) to \( \mathcal{H} \) is said to be complete if \( \text{dom} \phi \) is unbounded and maximal if there does not exist another pair \( \phi' \) such that \( \phi \) is a truncation of \( \phi' \) to some proper subset of \( \text{dom} \phi' \). For more details about solutions to hybrid systems, see [10].

**Proposition 3.2.** (Properties of solutions) For each \( \xi \in C \cup D \), every maximal solution \( \chi = (x, q) \) to the hybrid system \( \mathcal{H} = (C, F, D, G) \) in (5) with \( \chi(0, 0) = \xi \) is complete.

Our goal is to show that the solutions \( \chi \) to \( \mathcal{H} \) in (5) are such that the compact set \( A \) in (3) is asymptotically stable. To this end, we employ the following stability notion for general hybrid systems [10].

**Definition 3.3 (Stability):** A compact set \( A \subset \mathbb{R}^n \) is said to be

- stable if for each \( \varepsilon > 0 \) there exists \( \delta > 0 \) such that each solution \( \chi \) with \( |\chi(0, 0)|_A \leq \delta \) satisfies \( |\chi(t, j)|_A \leq \varepsilon \) for all \((t, j) \in \text{dom} \chi \);
- attractive if there exists \( \mu > 0 \) such that every maximal solution \( \chi \) with \( |\chi(0, 0)|_A \leq \mu \) is complete and satisfies \( \lim_{(t, j) \in \text{dom} \chi(t, j) \to \infty} \chi(t, j)|_A = 0 \);
- asymptotically stable if \( A \) is stable and attractive;
- globally asymptotically stable if the attractivity property holds for every point in \( C \cup D \).

The following result on the structural properties of \( \mathcal{H} \) in (5) is key for robust stability, see [10].

**Lemma 3.4:** The closed-loop system \( \mathcal{H} \) given by (5) satisfies the hybrid basic conditions, i.e., its data \((C, F, D, G)\) is such that

\[(A1) \text{ C and D are closed sets;}
\[(A2) \text{ F : } \mathbb{R}^n \Rightarrow \mathbb{R}^n \text{ is outer semicontinuous and locally bounded, and F(x) is nonempty and convex for all } x \in C;
\[(A3) \text{ G : } \mathbb{R}^n \rightarrow \mathbb{R}^n \text{ is continuous.}
\]

Using these conditions, we are now ready to show the following theorem, which states global asymptotical stability of the compact set \( A \) for the closed-loop system \( \mathcal{H} \).

**Theorem 3.5:** Consider the hybrid system \( \mathcal{H} \) in (5) with \( c, L, R, E > 0 \). Given a desired set-point voltage and current \((v_c^*, i_L^*)\), where \( v_c^* > E \) and \( i_L^* = \frac{v_c^*}{R} \), then the compact set

\[A = A_x \times \{0, 1\}\]

is globally asymptotically stable for \( \mathcal{H} \).

More importantly, since the hybrid closed-loop system in (5) satisfies the hybrid basic conditions (see Lemma 3.4) and the set \( A \) is compact, then, using [10, Theorem 7.21] we have that \( A \) is robustly asymptotically stable. We now

\[2\text{A set-valued map } S : \mathbb{R}^n \rightrightarrows \mathbb{R}^m \text{ is outer semicontinuous at } x \in \mathbb{R}^n \text{ if for each sequence } \{x_i\}_{i=1}^{\infty} \text{ converging to a point } x \in \mathbb{R}^n \text{ and each sequence } y_i \in S(x_i) \text{ converging to a point } y, \text{ it holds that } y \in S(x); \text{ see [15, Definition 5.4]. Given a set } X \subset \mathbb{R}^n, \text{ it is outer semicontinuous relative to } X \text{ if the set-valued mapping from } \mathbb{R}^n \text{ to } \mathbb{R}^m \text{ defined by } S(x) \text{ for } x \in X \text{ and } \emptyset \text{ for } x \notin X \text{ is outer semicontinuous at each } x \in X. \text{ It is locally bounded if, for each compact set } K \subset \mathbb{R}^n \text{ there exists a compact set } K' \subset \mathbb{R}^n \text{ such that } S(K') := \bigcup_{x \in K} S(x) \subset K'.\]
have completed the control design and formally established
a key closed-loop stability property, in particular, we showed
that the basin of attraction is $C \cup D$. It is worth noting
that, in addition to pertaining to simpler models (ignoring
mode 3) as mentioned before, previous literature lacks the
characterization of the basin of attraction.

C. Robustness to spatial regularization

For system (5), we have robustness to general perturba-
tions, but we only present results about spatial regularizar-
due to space constraints. When the system reaches its
desired steady state using the controller in Section III-B, very
fast switching may occur. To alleviate this problem, spatial
regularization is performed to the closed-loop system
(at the controller level). More precisely, $\gamma_0$ and $\gamma_1$ are modified by
using a constant factor $\rho$, with $\rho \in \mathbb{R}_{>0}$. The regularized
system will be denoted as $\mathcal{H}^\rho$, and its flow map is given by
the same equation as $\mathcal{H}$, i.e.,

$$\begin{bmatrix} \dot{x} \\ \dot{q} \end{bmatrix} \in \begin{bmatrix} F_\rho(x) \\ 0 \end{bmatrix} \quad (x, q) \in C_\rho,$$

where, now, the flow set is replaced by

$$C_\rho = \{(x, q) : x \in \tilde{M}_0, \gamma_0(x) \leq \rho, \ q = 0\} \cup \$$

$$\{(x, q) : x \in \tilde{M}_1, \gamma_1(x) \leq \rho, \ q = 1\}$$

Furthermore, the jump map is given by

$$x^+ = x \quad q^+ = G_q(x) \quad (x, q) \in D_\rho,$$

where, now, the jump set is replaced by

$$D_\rho = \{(x, q) : x \in \tilde{M}_0, \gamma_0(x) = \rho, \ q = 0\} \cup \$$

$$\{(x, q) : x \in \tilde{M}_1, \gamma_1(x) = \rho, \ q = 1\}$$

and

$$G_q(x) = \begin{cases} \{1\} & \text{if } q = 0, \gamma_0(x) \geq \rho \\ \{0\} & \text{if } q = 1, \gamma_1(x) \geq \rho \end{cases}$$

The new switching boundaries for a particular set of parameters
($x^* = (7, 3.27), E = 5V, R = 3\Omega, c = 0.1F, L = 0.2H$,
$p_{11} = \frac{5}{2}, p_{22} = \frac{5}{2}$, and $\rho = 2$) are shown in Figure 3.

**Theorem 3.6:** Under the assumptions of Theorem 3.5,
there exists $\beta \in KL$ such that, for each $\varepsilon > 0$ and each
compact set $K \subset \mathbb{R}^2$, there exists $\rho^* > 0$ guaranteeing
the following property: For each $\rho \in (0, \rho^*]$ every solution $x = (x, q)$ to $\mathcal{H}^\rho$ with $\chi(0,0) \in K \times \{0,1\}$ is such that its
$x$ component satisfies

$$|x(t,j)|_{A_{\mathcal{H}}} \leq \beta(|x(0,0)|_{A_{\mathcal{H}}},t+j) + \varepsilon \quad \forall (t,j) \in \text{dom} \chi. \quad (7)$$

The property asserted by Theorem 3.6 will be illustrated
numerically in Section IV-B.

IV. SIMULATION RESULTS

In this section, we present several simulation results.
First, the closed-loop system $\mathcal{H}$ is simulated for the ideal
case. Due to undesirable chattering, the spatial regularized
system $\mathcal{H}^\rho$ is simulated next. The simulations are performed
using $E = 5V, R = 3\Omega, c = 0.1F, L = 0.2H,$
and $P = \begin{bmatrix} \frac{5}{2} & 0 \\ 0 & \frac{5}{2} \end{bmatrix}$, unless noted otherwise, within the
**HYBRID EQUATIONS TOOLBOX** [16].

A. Simulating the closed-loop system

The results for initial conditions $x_0 = (0, 5)$ and $x_0 =
(5, 0)$ for the closed-loop system $\mathcal{H}$ are shown in Figure
4. As can be seen, the solutions converge from both initial
conditions to the set $A$.

![Simulated results for initial conditions](image)

Though not formally established in this paper, the closed-
loop system is robust to slowly varying parameters. To
illustrate this, a simulation is performed with a dynamically
changing set point $x^*$. Initially, $x^* = (7, 3.27)$, but when a
neighborhood of this value is reached, we linearly increase
$x^*$ from $(7, 3.27)$ to $(10, 6.67)$. This simulation is shown
in Figure 5. As it can be seen, the Boost converter follows the
reference well and eventually reaches a neighborhood of the
final $x^*$.

B. Simulating the spatially regularized closed-loop system

Now, the spatially regularized closed-loop system $\mathcal{H}^\rho$
is implemented. The results for initial conditions $x_0 = (0, 5),
q_0 = 1$ and $x_0 = (5, 0), q_0 = 0$, and where $\text{S}$ is only drawn for the simulation using $x_0 = (5, 0)$.

![Simulation results for spatial regularization](image)

To validate Theorem 3.6, more simulations are performed
in order to find a relationship between the spatially reg-
ularization parameter $\rho$ and $\varepsilon$ in Theorem 3.6. From the
simulation results shown in Table I, the relationship between
$\rho$ and $\varepsilon$, specifically, for $x^* = (7, 3.27)$, can now be
approximated as

$$\varepsilon \approx 0.9\rho \quad (8)$$
properties (e.g., stability, and robustness properties) of the closed-loop system.
